Announcements

- ► Today: value function iteration.
- Using:
 - 1. Grid search;
 - 2. Interpolation (grid search with functions filling in between nodes).
- ▶ Go through examples with neoclassical growth model.
- ► Homework assignment: do same with RBC model

Solving a Model

- When we say "solve a model" what do we mean?
 - 1. Find the equilibrium of the model.
 - 2. Generally, determine the policy functions.
 - 3. Determine the transition equations given the individual and aggregate state.
 - 4. i.e., aggregate up the policy functions and determine prices given distributions.
- Generically, this is hard: many states, non-linear decision rules, etc.

Solving a Model

- ► Generically, this is hard: many states, non-linear decision rules, etc.
- ► Much of quantitative macro is about finding "shortcuts" without sacrificing accuracy of solution (some we have seen):
 - 1. Planner's problem: use welfare theorems to remove prices from problem.
 - 2. Rational expectations & complete markets: Aggregate worker decision rules by assuming they make same predictions about future prices, and face same consumption risk.
 - 3. Exogenous wage distribution/prices: agents do not respond to decisions of other agents.
 - 4. Block Recursive Equilibrium: agents face an equilibrium with individual prices, i.e., no need to know distribution.
- ► Linearization: assume the economy is close enough to steady-state that transition equations (i.e., policy functions) are close to linear within small deviations.
- ► Value function iteration: discretize state space and solve model at "nodes" in state space.

Neoclassical Growth Model

Problem:

$$V(k) = \max_{k'} u(c) + \beta V(k') \tag{1}$$

$$c + k' = F(k) + (1 - \delta)k \tag{2}$$

- Assume power utility: $u(c) = \frac{c^{1-\sigma}-1}{1-\sigma}$
- ▶ Cobb-Douglas Production: $F(k) = k^{\alpha}$

Value Function Iteration

- Basic approach to value function iteration:
 - 1. Create grid of points for each dimension in state-space.
 - 2. Specify terminal condition V_t for t = T at each point in state-space.
 - 3. Solve problem of agent in period T-1: $V_t(y) = \max_x u(c(x)) + \beta E[V_{t+1}(x)].$
 - 4. x is policy function, which yields the largest value from $\{x_1, ..., x_N\}$, where N is the number of grid points.
 - 5. Check to see if function has converged, i.e., $|V_t V_{t+1}| < errtol$
 - 6. Update $V_{t+1} = V_t$
- Interpolation: same idea, but functions used to fill in between grid points.

Parameter Values

- ▶ Before we can solve the model (or write down grids) we need parameter values.
- ▶ Pick reasonable ones from the literature:
 - $\sim \alpha = 0.3$ (roughly capital share)
 - $ightharpoonup \sigma = 2$ (standard risk aversion)
 - $\delta = 0.1$ (annual depreciation 10%)
 - $\beta = 0.96$ (annual interest rate $\approx 4.2\%$)
- ▶ If we were estimating this model: we would evaluate the performance of the model given these parameters.
- i.e., how does it fit the data if we use this set of parameters.

Grids

- ► Want: smallest grids reasonable.
- ightharpoonup Find k^* , pick grids around this.
- Euler Equation

$$u'(c) = \beta[\alpha k^{\alpha - 1} + (1 - \delta)]u'(c')$$
 (3)

▶ In steady-state, $c = c' = c^*$

$$\rightarrow u'(c^*) = \beta[\alpha k^{*\alpha - 1} + (1 - \delta)]u'(c^*) \tag{4}$$

$$1 = \beta[\alpha k^{*\alpha - 1} + (1 - \delta)] \tag{5}$$

$$\left(\frac{1}{\alpha\beta} - \frac{1-\delta}{\alpha}\right)^{\frac{1}{\alpha-1}} = k^* \tag{6}$$

(7)

- For our parameter values, $k^* = 2.92$.
- ▶ Pick grids st $k, k' \in [0.66 * k^*, 1.5 * k^*]$
- Arbitrary, probably larger than needed.

Neoclassical Growth Model

Problem:

$$V(k) = \max_{k'} u(c) + \beta V(k') \tag{8}$$

$$c + k' = F(k) + (1 - \delta)k \tag{9}$$

- Assume power utility: $u(c) = \frac{c^{1-\sigma}-1}{1-\sigma}$
- ▶ Cobb-Douglas Production: $F(k) = k^{\alpha}$
- ▶ $k, k' \in \{k_1, ..., k_N\}$
- ▶ V_0 =? Safest bet to set it to zero at all k.

Value Function First Iteration

- Intuitively, take as given capital today (\bar{k}) , choose capital in the future that maximizes value.
- Problem:

$$V(\bar{k}) = \max_{k' \in k_1, \dots, k_N} u(c) + \beta V(k') \tag{10}$$

$$c + k' = F(\bar{k}) + (1 - \delta)\bar{k}$$
 (11)

► That is, policy function is k_i where i is the index of the optimal policy from the following:

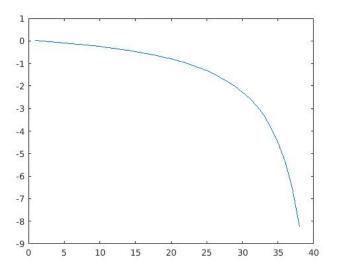

$$u(F(\bar{k}) + (1 - \delta)\bar{k} - k_1) + \beta \times 0 \tag{12}$$

$$u(F(\bar{k}) + (1 - \delta)\bar{k} - k_2) + \beta \times 0 \tag{13}$$

$$u(F(\bar{k}) + (1 - \delta)\bar{k} - k_N) + \beta \times 0 \tag{15}$$

Value Function First Iteration

▶ Value of $V_{t+1}(k')$ given $k = \bar{k}$ (x-axis is num. of grid pts.):

What is optimal choice?

Value Function First Iteration

- Now, check if problem has converged.
- ▶ What does this mean?
- ▶ The value in the current state is not changing over time.
- ▶ i.e., $V_t(k) \approx V_{t+1}(k)$.
- First iteration: it won't be.
- ► What do we do now?
- Update the continuation value:
- $ightharpoonup V_{t+1} = V_t$ for all k
- Solve same problem again.

Value Function Second Iteration

- ▶ Solved for V(k') in previous iteration.
- Again, faced with maximization problem given capital \bar{k} today:

$$V(\bar{k}) = \max_{k' \in k} u(c) + \beta V(k')$$
 (16)

$$c + k' = F(\bar{k}) + (1 - \delta)\bar{k}$$
 (17)

Note that the continuation value is not zero!

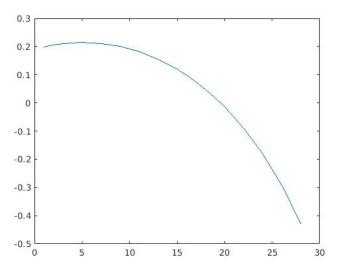

$$u(F(\bar{k}) + (1 - \delta)\bar{k} - k_1) + \beta V(k_1)$$
 (18)

$$u(F(\bar{k}) + (1 - \delta)\bar{k} - k_2) + \beta V(k_2)$$
 (19)

$$u(F(\bar{k}) + (1 - \delta)\bar{k} - k_N) + \beta V(k_N)$$
 (21)

Value Function Second Iteration

▶ Value of $V_{t+1}(k')$ given $k = \bar{k}$ (x-axis is num. of grid pts.):

What is optimal choice?

Value Function Second Iteration

- We check again to see if it has converged.
- ▶ is $V_t(k) \approx V_{t+1}(k)$.
- ► What do we do now?
- Update the continuation value:
- $ightharpoonup V_{t+1} = V_t$ for all k
- ► Solve same problem again.
- Keep doing this until the difference is very small.

Great, we're done!

- Not so fast: this isn't very accurate.
- Very slow if we have large numbers of states & grid points (scales exponentially).

Fundamental Problem

The reason we need to use a computer to solve this problem is that we *don't know* the function V(k).

$$V(k) = \max_{k'} u(c) + \beta V(k') \tag{22}$$

$$c + k' = F(k) + (1 - \delta)k$$
 (23)

- ▶ What is we approximate V(k) with other functions?
- Some useful properties we can pick these functions to have:
 - Continuous
 - Differentiable
- ▶ If our approximation is accurate enough, we can drop some grid points!

Again, take capital today as given $k = \bar{k}$. Grid search:

 $c + k' = F(\bar{k}) + (1 - \delta)\bar{k}$

$$V(\bar{k}) = \max_{k' \in k_1, \dots, k_N} u(c) + \beta V(k')$$

 $u(F(\bar{k}) + (1 - \delta)\bar{k} - k_1) + \beta V(k_1)$

(24)

(25)

(26)(27)

(28)

(29)

(30)

(31)

$$u(F(\bar{k}) + (1 - \delta)\bar{k} - k_N) + \beta V(k_N)$$

Call interpolated function
$$\hat{V}(k)$$
. Then

▶ Call interpolated function
$$\hat{V}(k)$$
. Then,

$$V(ar{k}) = \max_{k'} u(c) + eta \hat{V}(k')$$

$$\blacktriangleright$$
 Where k' solves

 $c + k' = F(\bar{k}) + (1 - \delta)\bar{k}$

$$u'(F'(\bar{k}) + (1-\delta)\bar{k} - k') = \beta \frac{\partial \hat{V}}{\partial k'}$$

Updating

We do exactly the same thing as before:

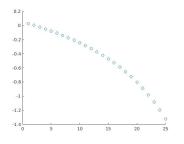

$$V(\bar{k}) = u(c(k'^*)) + \beta V(k'^*)$$
 (32)

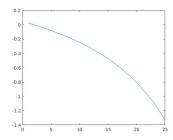

For each \bar{k} . Then, we check the convergence criteria:

$$|V_t - V_{t+1}| < errtol (33)$$

- ▶ How do we create the function $\hat{V}(k)$?
- ightharpoonup "Connect the dots" of $V_t(k)$ between all capital levels in order.

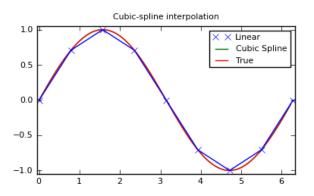

► Left is value function for grid search. Right is for (linearly) interpolated function:

- In constructing our function $\hat{V}(k)$, we need to choose an interpolation scheme.
- Roughly, what order function do we believe will be accurate enough to mimick the value function:
 - First-order (linear)
 - Third-order (cubic)
 - Fifth-order (quintic)
- Some other useful interpolation routines:
 - PCHIP (piecewise cubic hermite interpolating polynomial): shape-preserving (not "wiggly") continuous 3rd order spline with continuous first derivative.

► Choice DOES matter:

Polynomial Interpolation

- ▶ Suppose we have a function y = f(x) for which we know the values of y at $\{x_1, ..., x_n\}$.
- ► Then, the nth-order polynomial approximation to this function *f* is given by

$$f(x) \approx P_n(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_1 x + a_0$$
 (34)

- ▶ Then, we have a linear system with *n* coefficients.
- ▶ We could write this as $y = X\beta$. Look familiar?

Polynomial Interpolation

We solve

$$\begin{bmatrix} 1 & x_0 & x_0^2 & \dots & x_0^n \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & x_n & x_n^2 & \dots & x_n^n \end{bmatrix} \begin{bmatrix} a_0 \\ \vdots \\ a_n \end{bmatrix} = \begin{bmatrix} y_0 \\ \vdots \\ y_n \end{bmatrix}$$
(35)

- \triangleright For $a_0, ..., a_n$
- What's the example we are all familiar with? Linear regression: $y = \alpha + X\beta$.
- ▶ In practice, this is computationally expensive, but this is the intuition.

Great, we're done!

- Not so fast: how do we handle expected values?
- ▶ Depends on expectation.
- ▶ Need an accurate way to perform numerical integration.

Stochastic Neoclassical Growth Model

Problem:

$$V(z,k) = \max_{z'} u(c) + \beta E[V(z',k')]$$
 (36)

$$c + k' = e^z F(k) + (1 - \delta)k$$
 (37)

$$z' = \rho z + \epsilon \tag{38}$$

$$\epsilon \sim N(0, \sigma_{\epsilon})$$
 (39)

- Assume power utility: $u(c) = \frac{c^{1-\sigma}-1}{1-\sigma}$
- ▶ Cobb-Douglas Production: $F(k) = k^{\alpha}$
- Make sure your process for z stays non-negative.

Expectations with AR(1) Process

- Approximate a continuous AR(1) process with a markov process:
- ► Create grid of potential z values $\{z_1, ..., z_N\}$, approximate AR(1) process through transition probabilities.

$$E[z_t] = E[\rho z_{t-1} + \epsilon_t] = 0 \tag{40}$$

$$V[z_t] = V[\rho z_{t-1} + \epsilon_t] = \rho^2 \sigma_z^2 + \sigma_\epsilon^2$$
 (41)

$$\to (1 - \rho^2)\sigma_z^2 = \sigma_\epsilon^2 \tag{42}$$

- ▶ Define this process $G(\bar{\epsilon})$
- ► Tauchen (1986):

$$z_N = m(\frac{\sigma_\epsilon^2}{1 - \rho^2}) \tag{43}$$

$$z_1 = -z_N \tag{44}$$

$$z_2, ..., z_{N-1}$$
 equidistant (45)

Expectations with AR(1) Process

► Tauchen (1986):

$$z_N = m(\frac{\sigma_\epsilon^2}{1 - \rho^2}) \tag{46}$$

$$z_1 = -z_N \tag{47}$$

$$z_2, ..., z_{N-1}$$
 equidistant (48)

ightharpoonup Create an $n \times n$ transition matrix Π using probabilities

$$\pi_{ij} = G(z_j + d/2 - \rho z_i) - G(z_j - d/2 - \rho z_i)$$
 (49)

$$\pi_{i1} = G(z_1 + d/2 - \rho z_i) \tag{50}$$

$$\pi_{iN} = 1 - G(z_N + d/2 - \rho z_i) \tag{51}$$

Expectations Generally

- Expected values also need to be calculated carefully.
- Continuation value from before:

$$E[V(z,k')] (52)$$

- ▶ If not an AR(1)/markov process, need to approximate integral.
- ▶ Generically, pick function f and weights w_i

$$E[V(z,k')] = \int_a^b f(x)dx \approx \sum_{i=1}^N w_i f(x_i)$$
 (53)

- \triangleright x_i may be known or picked optimally.
- We will return to this in the future.

Next Time

► Calibration and RBC extensions.
